ABSTRACT
This study examines the effect of profitability and liquidity on CSR disclosure and its implication on economic consequences. This study was driven by the inconsistency of the results of previous studies in testing the factors that influence the CSR disclosure. This study used the CSR disclosure to measure Corporate Social Responsibility disclosure index (CSRD) based on the index of the Global Reporting Initiatives G4 Guideline (GRI G4). The results show that profitability has a significant and positive effect on CSR disclosure, while liquidity does not affect CSR disclosure. Furthermore, CSR disclosure has a negative effect on the bid-ask spread, CSR disclosure has a positive effect on trading volume, while CSR disclosure doesn’t affect stock price volatility. This study implies as the following: companies that have high profitability should have strong commitment to disclose corporate social responsibility because it can help reduce information asymmetry.

1. INTRODUCTION
CSR disclosure is one type of sustainability reporting which explains the various aspects of the company ranging from social, environmental, and financial. All these cannot be described implicitly by a company’s financial statements (Jitaree, 2015). In general, the implementation of developing business ethics is realized in the implementation of CSR, which is a form of sensitivity, awareness, and CSR to help provide benefits to society and the environment in which it operates.

The development of CSR in this decade has been followed by strengthening the existence of CSR into normative obligations in several countries. Indonesia is one of the countries has stipulated for the companies with the existence of CSR. Therefore, CSR in Indonesia has experienced a fast development. The demand on companies to provide information

* Corresponding author, email address: dodyhapsoro@gmail.com
that is transparent and accountable and good corporate governance has increasingly forced the companies to provide information about their social activities. The obligation to implement the CSR is in the Law of the Republic of Indonesia Number 40 of 2007 concerning Limited Liability Companies Article 74. Article 74 stated that companies that conduct business activities in the field/related to the natural resources required to conduct a social and environmental responsibility.

A study of the factors affecting the CSR disclosure in developing countries have provided the researchers with different results. For example, a study conducted by Khelif et al. (2015) in Bangladesh, found that the profitability significantly positive effect on the CSR disclosure. However, a study conducted by Adeyemo et al. (2013) to the companies listed on the Indonesia Stock Exchange (IDX) showed that the profitability does not a significantly positive effect on the CSR disclosure. The study conducted by Hussainey et al. (2011) and Ekowati et al. (2014) demonstrated that the profitability significantly positive effect on CSR disclosure, but liquidity hasn’t proven its effect on CSR disclosure.

The inconsistency of the findings of previous studies prompted the researchers to examine the factors that affect the CSR disclosure. The researchers used the variables used such as profitability and liquidity. Profitability can be seen from the ratio of return on equity (ROE). ROE illustrates the ability of a company’s profitability. The higher the level of profitability of the company, the greater disclosure of social information (Nurkhin, 2009). Liquidity is the ratio to determine the company’s ability to pay short-term obligations. Almilia and Devi (2007) stated that a high level of liquidity indicates a strong financial condition of the company so that it will encourage companies to conduct high social responsibility disclosures.

Economic consequence is the impact of accounting reports on the behavior of business decision-makers, governments, investors and creditors. Furthermore, the financial statement is a means of communicating financial information to parties outside the corporation. The financial statements are expected to provide information to investors and creditors in making decisions related to investment funds.

Signaling theory emphasizes the importance of information released by the company to reduce the information asymmetry that occurs between stakeholders and management. Information asymmetry is the difference between information obtained by one party to the other party in economic activity. The information dissemination which is not balanced will cause information asymmetry. CSR disclosure in this case is expected to be useful information for investors and stakeholders for decision-making (Ramadhani, 2014).

This study examined the effect of profitability and liquidity on disclosure of CSR disclosure and the effect of CSR disclosure on economic consequences. In this study, the proxy used to measure the economic consequences consist of bid-ask spreads, trading volume, and stock price volatility. Liao (2009) stated that the desire to reduce the information asymmetry can be done by testing and researching the bid-ask spread. When the bid-ask spread decreases, it can be concluded that the information asymmetry is declined.

Trading volume is an instrument that can be used to look at the stock market reaction to information through a parameter volume of stocks traded in the capital market (Avgouleas & Degiannakis, 2009). The higher stock trading volume indicates that the stock is more attractive to investors. In addition to it, stock price volatility is a statistical measure of fluctuations in stock prices over a specified period. The high and low stock price volatility depending on the information obtained by investors about the stock price information either from inside or from outside of the company. The lower stock price volatility indicates the smaller of the information asymmetry.

2. THEORETICAL FRAMEWORK AND HYPOTHESIS

Theoretical Framework

According to Ismail (2009), CSR disclosure is a business concern on the environment, either the environment in the course of business and outside business activities, such as the safety of workers and handling of the waste produced so as not to disrupt the surrounding community. The people in the business environment should provide appropriate responses undertaken by the company’s business activities.

In this context, CSR is a vision of business accountability. In addition, CSR focuses on environmental protection, safety, and development of communities and society in general, both now and in the future. CSR
concept directs that a company will not be able to last long if the company isolate and confine himself from surrounding communities (Ismail, 2009).

Legitimacy theory provides an important view of the practice of CSR disclosure. Mousa and Hassan (2013) stated that legitimacy theory is based on the idea that to continue operating successfully, corporations must act within the bounds of what society identifies as socially acceptable behavior. By ensuring that the company has been working within accepted norms and rules of society, it can also imply the existence of a social contract that is the claim of the company as part of a social system must constantly interact with the social environment as well as running the norms contained therein. To meet the social demands, the company should always pay attention to the issues that developed in the community. They also have to constantly make the stakeholders sure and believes that the company has operating activities in accordance with the provisions and norms that exist.

Stakeholder theory is a system that is explicitly based on the idea of an organization and its environment. The company is not only responsible to the owners (shareholders) to the extent of the economic indicators (economic focused) but has been shifted to the broader i.e. in the realm of social (stakeholders) to take into account social factors (social dimensions), so that arises the term of social responsibility. Stakeholder theory discusses matters relating to the interests of various parties. Stakeholders will be a control tool for the company to evaluate the activities of the company. Company awareness about the importance of stakeholder existence will make the company continue to innovate and evaluate so that the company can develop.

According to Zeff (1978), economic consequence is the impact of accounting reports on business, government and creditor decision-making behavior. In a study conducted by Leuz and Verrecchia (2000) entitled “The Economic Consequences of Increased Disclosure”, the proxy used to measure economic consequences is bid-ask spreads, volume trading, and stock price volatility. Bid-ask spreads are the difference between the highest purchase price and the lowest selling price. Trading volume is the total number of security or an entire market that was traded during a given period. Stock price volatility indicator that is most often used by changes in trends in the market place.

The next is information. It is a fundamental requirement for investors and potential investors. With timely, complete, accurate and relevant information, this information can allow investors to make rational decisions. Disseminating the unbalanced information can cause information asymmetry. Parties which have no information will be the losers, while those who have the information would be better off.

Research Framework
The research framework is described as follows:

Hypothesis Development
The Effect of Profitability on the CSR Disclosure
The relationship between profitability and CSR disclosure is based on legitimacy theory which states that CSR disclosure is carried out to get a positive and legitimate assessment of society. Profitability is, in this case, the ability of a company to earn profits in certain periods. Profitability gives confidence to companies to voluntarily disclose social responsibility. The higher the level of profitability will further motivate companies to disclose CSR to gain

![Figure 1 Research Framework](image-url)
legitimacy and positive value of stakeholders. Some studies have been done examining the effect of profitability on CSR. For example, a study by Nurkin (2009) provides evidence that profitability positively affects the CSR. The study of Nurkin (2009) in line with a study conducted by Yintayani (2011), Hussainey et al. (2011) and Ekowati et al. (2014). As argued with evidence above, this study formulates the hypothesis as follows.

\[ H_1: \text{Profitability positively affects the CSR disclosure} \]

**The Effect of Liquidity on the CSR Disclosure**

Liquidity shows the relationship between the cash and other current assets of a company with current liability. Liquidity is the ratio to determine the company’s ability to pay short-term obligations. Companies that have high liquidity tend to do more social activities as a signal to investors that companies have better performance than other companies. With the increasing disclosure of CSR, it will be increasingly attractive for investors to invest in companies and show that the company is more credible in the eyes of investors.

The argument above has been provided with the evidence. For example a study by Syahrir and Suhendra (2010) found that the liquidity positively affects on CSR disclosure. However, a study Rahajeng (2010) found that liquidity does not affect the disclosure of CSR. Although the two previous studies are not consistent each other, in this study, the researcher formulates the hypothesis as follows:

\[ H_2: \text{Liquidity positively affects the CSR disclosure} \]

**The Effect of CSR Disclosure on the Economic Consequences**

CSR disclosure is an example of signaling theory that can reduce the level of information asymmetry (Spence, 2002). CSR activities can enhance corporate accountability and transparency (Cui et al., 2012). Increased transparency and accountability results in more information being given to the public. Therefore, the outsiders know more information about the company. With the increasing number of CSR disclosures, investors can assess the company more precisely so that the bid-ask spread will decrease, trading volume increases and stock price volatility decreases. Based on the above arguments, the researchers formulate the three hypotheses as well as follows:

\[ H_{3a}: \text{CSR disclosure negatively affects the bid-ask spread}. \]
\[ H_{3b}: \text{CSR disclosure positively affects the trading volume}. \]
\[ H_{3c}: \text{CSR disclosure negatively affects the stock price volatility}. \]

### 3. RESEARCH METHOD

#### Population and Sampling Techniques

The population consists of all companies listed on the Indonesian Stock Exchange (IDX) in 2017. The reason for choosing 2017 is that the research was carried out after the publication of G4 Sustainability Reporting Guidelines on Disclosure of GRI (Global Reporting Initiatives) in 2013. Therefore, the researchers expected that the results would reflect the current state of affairs. The sample was taken using a purposive sampling method. The sample in this study was determined based on the following criteria:

2. The company publishes a sustainability report or disclose the corporate social responsibility information in annual reports.
3. The company has complete data of stock price and the value of individual stock prices during the observation period.
4. The company has data of bid-ask spread, trading volume, and stock price volatility.

#### Research Variable

The first model of this study used profitability and liquidity as the independent variables and CSR disclosure as the dependent variable. The second model of this study used CSR disclosure as the independent variable and the economic consequences which consist of a proxy bid-ask spreads, trading volume, and stock price volatility as the dependent variables.

#### Operational Definitions

**Profitability**

Profitability is a measure of a company’s ability to earn income (profit) at a certain period. Profitability in this study will use the proxy of return on equity (ROE). The ROE calculation formula is as follows:

\[ \text{Return on Equity (ROE)} = \frac{\text{Net Profit After Tax}}{\text{Total Equity}} \]

**Liquidity**

Liquidity is a measure of a company’s ability to meet its short term obligations. The level of liquidity in this study was measured by the
current ratio (CR). The liquidity calculation formula is as follows:

\[
\text{Current Ratio} = \frac{\text{Current Assets}}{\text{Current Liabilities}}
\]

**CSR Disclosure**

This study measured CSR disclosure using proxy CSRDI (corporate social responsibility disclosure index) based on the index of Global Reporting Initiatives G4 (GRI G4) Guideline on Disclosure. The CSRDI consists of six variables, based on GRI guidelines dimensions (economic, environment, labor, society, human rights, and product responsibility). GRI indicator was chosen because it is the international guidelines that have been recognized by many companies in the world. This approach used dichotomous approach, i.e. each item of CSR in the research instrument-rated 1 if disclosed and rated 0 if not disclosed. Furthermore, the scores of each item were summed to obtain the overall score of each company. The CSRDI calculation formula is as follows:

\[
\text{CSRDI}_j = \sum X_{ij} / n_{ij}
\]

Description:

CSRDI\_j = Corporate Social Responsibility Disclosure Index company \_j

\(n_{ij}\) = Number of items for company \_j, \(n = 91\)

\(X_{ij}\) = Dummy variable: 1 = if the item i disclosed; 0 = if the items were not disclosed. Thus, 0 < CSRDI\_j < 1

**Economic Consequences**

The economic consequence is the impact of accounting reports on the behavior of decision-making, although the accounting reports do not affect the cash flow. The economic consequence was proxied by bid-ask spreads, trading volume, and stock price volatility.

a. **Bid-Ask Spread**

Bid-ask spread is the difference between the highest purchase price that the buyer wants the stock and the lowest selling price offered by the seller of the stock. In this study, the measurement of bid-ask spreads using the following formula:

\[
\text{Spread}_{i,t} = \frac{(\text{bid}_{i,t}-\text{ask}_{i,t})/(\text{bid}_{i,t}+\text{ask}_{i,t})/2 \times 100}{n}
\]

**Description:**

\(\text{Spread}_{i,t}\) = The average difference between the highest purchase price and the lowest selling price daily of firm i for one year

\(\text{Bid}\) = The highest purchase price

\(\text{Ask}\) = The lowest selling price

b. **Stock Trading Volume**

Stock trading volume refers to the method used by Zhang et al. (2015), which is based on the average (mean) the volume of stock trading for one year. Stock trading volume calculation formula is as follows:

\[
\text{VPS}_{i,t} = \frac{\sum_{t=1}^{n} \text{VPS}_{i,t}}{n}
\]

Description:

\(\text{VPS}_{i,t}\) = The average daily stock trading volume of firm i for one year

\(\text{VPS}_{i,1}\) = Volume of daily stock trading firm i from the beginning of the year until the end of the year

\(n\) = Number of transactions day for a year

c. **Stock Price Volatility**

Stock price volatility is determined by calculating the standard deviation of a portfolio that occurred during the study period. Stock price volatility calculation formula is as follows:

\[
\sigma_i^2 = \text{Variance}
\]

\(\sigma_i\) = Deviation standard

\(X_{i,t}\) = Each daily stock price of firm i for one year

\(\overline{X}_t\) = Average daily stock price of firm i

**Data Collection Methods**

The data were collected by empirical data in the form of a data source created by the company in the form of annual reports and sustainability reporting.

**Method of Analysis**

The analytical method used in this study includes a descriptive analysis and classical assumption test.

1. **Descriptive Analysis**

Descriptive analysis is used to provide an overview of the study variables. Descriptive
statistics were used in this study include the mean, median, minimum, maximum, and standard deviation.

2. Classical Assumption Test
   The classical assumption test is performed to determine the data that are worth to be analyzed. Testing data in this study include:

   **Normality Test**
   The normality test aims to test whether, in the regression model, confounding or residual variables were normally distributed. This study used the Kolmogorov-Smirnov (KS) test. A good regression model is to have a normal or near-normal distribution. This testing is done by looking at the statistical significance value resulting from the calculation. If the significance value > 0.05, the regression equation were normally distributed.

   **Multicollinearity Test**
   The multicollinearity test aims to test whether the regression model found a correlation between free variables (independent). If the results show the value of Variance Inflation Factor (VIF) ≥ 10 means there any multicollinearity, otherwise if VIF < 10 means no multicollinearity.

   **Autocorrelation Test**
   The autocorrelation test aims to test whether in the linear regression model any correlation between confounding error in period t with confounding error in period t-1 (previously). Detection of the autocorrelation can be seen from the figures DW (Durbin-Watson). If DU < DW < (4-DU) then there is no autocorrelation (Ghozali, 2011: 110).

   **Heteroscedasticity Test**
   The heteroscedasticity test aims to test whether in the regression model occurred inequality residual variance from one observation to another observation. This test also aims to test whether in the regression model occurred inequality standard deviation value of the dependent variable at each independent variable. A good regression model is a model that homoscedasticity or not happen heteroscedasticity. This study uses a Plot Graph and the basic analysis are:
   1. If there is a specific pattern, such as dots forms a pattern of certain existing regular (wavy, widened, then narrowed) would indicate there was heteroscedasticity.
   2. If there is no clear pattern and the point spread above and below the number on the Y axis, then there is no heteroscedasticity.

4. DATA ANALYSIS AND DISCUSSIONS

   **Sample Selection**
   The population consists of all companies listed on the Indonesian Stock Exchange (IDX) in 2017. It was selected using a purposive sampling method. The number of companies whose data have been obtained by researchers until June 5, 2015, and has met all the criteria of sampling are as many as 62 companies.

   **Descriptive Analysis**
   Descriptive statistical analysis results are shown on Table 1.

   **Profitability**
   The average value of ROE is equal to 15.3824. This shows that the average company’s ability to generate earnings from its capital amounted to 15.38%. The minimum value is 0.14 or 0.14% of the company’s equity, while the maximum value is equal to 75.4 or 75.4%. This means the company can generate a net profit up to 75.4% of the total equity of the company.

   **Liquidity**
   Liquidity variable (CR) has the lowest value of 0.32, the maximum value of 7.90, the average value of 1.9181 and a standard deviation of

1.40715. Liquidity variable as measured by CR showed an average of 1.9181. This means that the average company listed on the IDX has current assets amounted to 1.9181 from all current debts.

**Corporate Social Responsibility (CSR)**

The CSR disclosure index variable has the lowest value of 0.14, the maximum value of 0.88, the average value of 0.4753 and a standard deviation of 0.19509. On average CSR disclosure is 0.4753 or 47.5% or over a period on average the company has revealed the social responsibility as much as 47.5% in the annual report.

**Bid-Ask Spread**

Bid-ask spread (BAS) variable has an average value of 1.8742, the minimum value of 0.08, the maximum value of 4.81 and a standard deviation of 1.13284. It shows that the average difference between the highest buying price and selling price lowest daily stock company during the year amounted to 1.8742.

**Trading Volume**

Trading volume (TV) variable has an average value of 10,313,470.23, minimum value of 935.25, the maximum value of 92,091,041 and a standard deviation value of 17,781,828.17. It shows that the average daily stock trading volume of the company for one year is 10,313,470.23.

**Stock Price Volatility**

Stock price volatility (SPV) variable has an average value of 635.3167, a minimum value of 7.77, the maximum value of 5427.04 and a standard deviation value of 969.76989. It shows that the average daily stock price of the company for one year is equal to 635.3167.

**Classical Assumption Test**

Classical assumption test consisting of normality test, multicollinearity test, autocorrelation test, and heteroscedasticity test. The result of the classical assumption test is shown on Table 2.

**Normality Test**

Results of Kolmogorov-Smirnov (KS) test in Model 1 indicates that the value Asymp. Sig. (2-tailed) is equal to 0.967. While the test results in Model 2 show that the value Asymp. Sig. (2-tailed) respectively are 0.678, 0.700 and 1.00. Based on test results, it can be concluded that the residual data in the regression model are normally distributed because of the value Asymp. Sig. (2-tailed) greater than 0.05.

**Multicollinearity Test**

Based on test results, the value of VIF is less than 10 or equal to 1.009. Based on these results, it can be concluded that there is no strong correlation between the independent variables.

**Autocorrelation Test**

From the results of regression in the first model obtained Durbin Watson value of 1.825 or writable 1.6561 < 1.825 < 2.3439. Therefore, it can be concluded that in the first model did not happen autocorrelation. Furthermore, in the second model obtained Durbin Watson value of 1.636, 2.139 and 2.041 somewhere in between Du at 1.6216 and (4-Du) of 2.3784. It was, therefore, can be concluded that the second model did not happen autocorrelation.

**Heteroscedasticity Test**

In the scatterplots graph showed that the dots spread randomly and spread both in the above and below the number 0 on the Y-axis. Based on this can be concluded that in the regression model did not happen heteroscedasticity making it feasible to be continued to test the hypothesis.

**Discussion**

The results of the Model 1 regression test are shown on Table 3.

Based on the results of the regression analysis above, the regression equation models produced in this study are as follows: Y = 0.767 + 0.113X1 + 0.003X2.

Source: Processed data, 2019

- **Profitability Positively Affects the CSR Disclosure**
  
The test result of Hypothesis 1 demonstrated a significant level of 0.007. Sig 0.007 < 0.05. This means that the first hypothesis (H1) is supported. High profitability will provide an opportunity for management to perform and disclose corporate social responsibility widely. The test result is consistent with the study of Elsakit and Worthington (2014) which states that profitability affects the CSR disclosure. In addition, the results of the study are in line with the theory of legitimacy which states that to be able to operate successfully, companies must act and behave socially acceptable through CSR disclosure.

- **Liquidity Positively Affects the CSR Disclosure**
  
The test result of Hypothesis 2 demonstrated a significant level of 0.491. Sig 0.491 > 0.05. This means that the second hypothesis (H2) is not supported. The test results are consistent with research conducted by Wicaksono (2011), Rahajeng (2010), Hussainey et al. (2011) and Ekowati et al. (2014) which found no evidence that the liquidity affects the CSR disclosure. High liquidity makes companies more concerned to repay the debt rather than social activities (Hussainey et al., 2011 and Ekowati et al., 2014). The results of the study are not in line with the theory of legitimacy because even though they have a high level of liquidity, companies do not necessarily act and behave socially acceptable through CSR disclosure. Before, the liquidity does not affect the broad of CSR disclosure.

  
The results of the Model 2.1 regression test are shown on Table 4.

  
  Based on the results of the regression analysis above, the regression equation models produced in this study are as follows: \( Y = 2.565 - 1.455X_1 \).

- **CSR Disclosure Negatively Affect the Bid-Ask Spread**
  
The test result of Hypothesis 3 demonstrated the significance level of 0.049. Sig 0.049 < 0.05. This means that the third hypothesis (H3) which states that CSR disclosure negatively affects the bid-ask spread is supported. The result of this study supports the findings of Hapsoro (2006) which states that the company’s commitment to increase the level of voluntary disclosure is proven to reduce the bid-ask spread which is one of the essential elements of the information asymmetry component of the cost of capital. Ramadhani (2014) also states that all dimensions of CSR disclosure can reduce information asymmetry as measured by the bid-ask spread. The results of the Model 2.2 regression test are shown on Table 5.
Based on the results of the regression analysis above, the regression equation models produced in this study are as follows: \( Y = 12.034 + 4.306X1 \).

5. CONCLUSION, IMPLICATION, SUGGESTION, AND LIMITATIONS

**Conclusion**

Based on the test results and the previous discussion, this study concluded as the following:

1. The first hypothesis \((H_1)\) is accepted. The result of hypothesis testing shows that profitability has a positive effect on the CSR disclosure. The results of this study are in line with the research of Elsakit and Worthington (2014).

2. The second hypothesis \((H_2)\) is rejected. The result of hypothesis testing shows that liquidity does not affect the CSR disclosure. High liquidity encourages companies to pay more to pay their debts than to conduct corporate social activities (Hussainey et al., 2011 and Ekowati et al., 2014). In addition, the underlying reason for liquidity does not affect the CSR disclosure is the lack of stakeholder attention to liquidity quality. Investors assume that a liquid company does not necessarily have a high profit. Liquidity further illustrates the company’s ability to fulfill its responsibilities in the short term. Therefore liquidity does not affect the extent of CSR disclosure.
3. The third hypothesis (H3) is accepted. The result of hypothesis testing shows that the CSR disclosure negatively influences the bid-ask spread. The results of this study are in line with Hapsoro and Fadhilla (2017) study which stated that the company’s commitment to increase the level of voluntary disclosure of information proved to decrease the bid-ask spread which is one of the important elements of the information asymmetry component.

4. The fourth hypothesis (H4) is accepted. The result of hypothesis testing shows that the CSR disclosure has a positive effect on trading volume. This is in line with the research of Chetty et al. (2015) and Ramadhanii (2014) stated that CSR disclosure of the company’s annual report affects trading volumes.

5. The fifth hypothesis (H5) is rejected. The result of hypothesis testing shows that the CSR disclosure has no positive effect on stock price volatility. This is in line with Ramadhanii’s (2014) study which argued that stock price volatility is believed to be influenced by various factors other than CSR disclosure.

Implication
The results of this study provides some implications as follows:
1. Companies with high profitability should have a high commitment to disclose corporate social responsibility because the company is believed to be able to overcome the costs of CSR disclosure. With the high CSR disclosure is expected to reduce the possibility of conflict between companies and communities as a negative impact arising from the existence of companies in an environment.

2. Companies need to increase their commitment to disclose their corporate social responsibility as CSR disclosure has a negative effect on bid-ask spreads and has a positive effect on trading volumes. This commitment will increase investor interest in the activity of the capital market because both buyers and stock sellers have the same information thus reducing the information asymmetry between them.

Suggestion
Based on the results of the study as well as matters related to the limitations of the study, the researchers suggest for further research as follows:
1. to multiply the number of samples so that the conclusion made possible to be generalized.
2. to use a longer observation period in order to obtain information on actual conditions.
3. to add or use other variables that relevant in the CSR disclosure, such as management ownership, the board size, and so forth.

Limitation
This study has some limitations, namely:
1. The number of samples obtained is relatively small. This is because this study only used a one-year observation period, which is 2017.
2. Although in Law No. 40 of 2007 concerning Limited Liability Company article 74 stated that companies that carry out business activities in the field/related to natural resources are required to carry out social and environmental responsibility, but not all companies have disclosed social and environmental responsibility.
